## Cheat Sheet: Python Data Structures Part-2

## Dictionaries

Dictionaries			
Package/Method	Description	Code Example	
Creating a Dictionary	A dictionary is a built-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in curly braces 1	Example:  1	
Accessing Values	You can access the values in a dictionary using their corresponding keys.	Syntax:  1  Value = dict_name["key_name"] ②  Example:  1  name = person["name"] 2  age = person["age"] ②	
Add or modify	Inserts a new key-value pair into the dictionary. If the key already exists, the value will be updated; otherwise, a new entry is created.	Syntax:  1	
del	Removes the specified key-value pair from the dictionary. Raises a KeyError if the key does not exist.	Syntax:  1    del dict_name[key]	
update()	The update() method merges the provided dictionary into the existing dictionary, adding or updating key-value pairs.	Syntax:  1	
clear()	The clear() method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.	Syntax:  1 dict_name.clear() 원  Example:  1 grades.clear() 원	
key existence	You can check for the existence of a key in a dictionary using the in keyword	Example:  1    if "name" in person: 2    print("Name exists in the dictionary.")	
copy()	Creates a shallow copy of the dictionary. The new dictionary contains the same key-value pairs as the original, but they remain distinct objects in memory.	Syntax:  1   new_dict = dict_name.copy()	
keys()	Retrieves all keys from the dictionary and converts them into a list. Useful for iterating or processing keys using list methods.	Syntax:  1 keys_list = list(dict_name.keys())  Example:  1 person_keys = list(person.keys())	
values()	Extracts all values from the dictionary and converts them into a list. This list can be used for further processing or analysis.	Syntax:  1  values_list = list(dict_name.values()) ②  Example:  1  person_values = list(person.values()) ②	
items()	Retrieves all key-value pairs as tuples and converts them into a list of tuples. Each tuple consists of a key and its corresponding value.	Syntax:  1 items_list = list(dict_name.items()) ②  Example:  1 info = list(person.items()) ②	

## Sets

Package/Meth	d Description	Code Example

add()	Elements can be added to a set using the 'add()' method. Duplicates are automatically removed, as sets only store unique values.	Syntax:           1         set_name.add(element)         ②           Example:           1         fruits.add("mango")         ②
clear()	The 'clear()' method removes all elements from the set, resulting in an empty set. It updates the set in-place.	Syntax:   1
copy()	The 'copy()' method creates a shallow copy of the set. Any modifications to the copy won't affect the original set.	Syntax:  1
Defining Sets	A set is an unordered collection of unique elements. Sets are enclosed in curly braces '()'. They are useful for storing distinct values and performing set operations.	Example:  1   empty_set = set() #Creating an Empty 2   Set fruits = {"apple", "banana", "orange"}
discard()	Use the 'discard()' method to remove a specific element from the set. Ignores if the element is not found.	Syntax:  1 set_name.discard(element) ②  Example:  1 fruits.discard("apple") ②
issubset()	The 'issubset()' method checks if the current set is a subset of another set. It returns True if all elements of the current set are present in the other set, otherwise False.	Syntax:  1  is_subset = set1.issubset(set2)
issuperset()	The 'issuperset()' method checks if the current set is a superset of another set. It returns True if all elements of the other set are present in the current set, otherwise False.	Syntax: is_superset = set1.issuperset(set2)  Example:  1  is_superset = colors.issuperset(fruits) &
pop()	The 'pop()' method removes and returns an arbitrary element from the set. It raises a 'KeyError' if the set is empty. Use this method to remove elements when the order doesn't matter.	Syntax:  1 removed_element = set_name.pop() &  Example:  1 removed_fruit = fruits.pop() &
remove()	Use the 'remove()' method to remove a specific element from the set. Raises a 'KeyError' if the element is not found.	Syntax:  1 set_name.remove(element) ②  Example:  1 fruits.remove("banana") ②
Set Operations	Perform various operations on sets: 'union', 'intersection', 'difference', 'symmetric difference'.	Syntax:  1
update()	The 'update()' method adds elements from another iterable into the set. It maintains the uniqueness of elements.	Syntax:  1 set_name.update(iterable) ②  Example:  1 fruits.update(["kiwi", "grape"]) ②
